Computer Vision Laboratory **Unseen Spacecraft Pose Estimation**

Baseline solution by implementing a machine learning
framework with target models included

Bachelor's Thesis in Computer Science

Author: Jérémy Chaverot
Supervisor: Prof. Dr. Mathieu Salzmann
Advisor: Dr. Andrew Price, PhD. Chen Zhao
Semester: Fall 2023

I hereby confirm that I am the sole author of the written work here enclosed and that I have compiled it in my own words. Parts excepted are corrections of form and content by the advisors.

Lausanne, Switzerland, 05.01.24

Jérémy Chaverot

Acknowledgments

Before delving into the topic, I'd like to express some acknowledgments. First and foremost I must thank my advisors Andrew Price and Chen Zhao for accepting my request to take part in a semester project under their guidance. I am grateful to have been able to practice my skills with them, and can only hope that the feeling is mutual. Moreover I would also like to thoroughly thank my friends and family for supporting me in my academic journey, despite a rather unstable start in my studies.

3.4 Pose refinement

3.5 Results on LINEMOD

4 Implementation of the model

4.1 Data loader

abstract base classes (ABC) each and every abstract method

4.2 Issues and proposed solutions

4.2.1 Issues No. 1

4.2.2 Issues No. 2

5 Experimental results and analysis

5.1 Spacecraft dataset characteristics

5.2 Vizualisation of results

5.3 Evaluation metrics

To appreciate the quality of the estimations, the most widely used pose error functions are the Average Distance of Model Points (ADD) and the Average Closest Point Distance (ADD-S) metrics, both introduced by Hinterstoisser et al. [3]. For an object model \mathcal{M} , we compute the average distance to the corresponding model point. Therefore the error of an estimated pose $\hat{\mathbf{P}} = (\hat{\mathbf{R}}, \hat{\mathbf{T}})$ w.r.t. the ground truth pose $\bar{\mathbf{P}} = (\bar{\mathbf{R}}, \bar{\mathbf{T}})$ is calculated as follows:

$$e_{\text{ADD}}(\hat{\mathbf{P}}, \bar{\mathbf{P}}, \mathcal{M}) = \text{avg}_{x \in \mathcal{M}} \left\| \bar{\mathbf{P}}x^* - \hat{\mathbf{P}}x^* \right\|_2^1 \quad (5.1)$$

$$= \text{avg}_{x \in \mathcal{M}} \left\| (\bar{\mathbf{R}}x + \bar{\mathbf{T}}) - (\hat{\mathbf{R}}x + \hat{\mathbf{T}}) \right\|_2 \quad (5.2)$$

When the model \mathcal{M} has symmetries that leads to no indistinguishable views, the error is computed as the average distance to the closest model point:

$$e_{\text{ADD-S}}(\hat{\mathbf{P}}, \bar{\mathbf{P}}, \mathcal{M}) = \text{avg}_{x_1 \in \mathcal{M}} \min_{x_2 \in \mathcal{M}} \left\| \bar{\mathbf{P}}x_1^* - \hat{\mathbf{P}}x_2^* \right\|_2 \quad (5.3)$$

$$= \text{avg}_{x_1 \in \mathcal{M}} \min_{x_2 \in \mathcal{M}} \left\| (\bar{\mathbf{R}}x_1 + \bar{\mathbf{T}}) - (\hat{\mathbf{R}}x_2 + \hat{\mathbf{T}}) \right\|_2 \quad (5.4)$$

It's important to point out that $e_{\text{ADD-S}}$ is more lenient compared to e_{ADD} , and should only be applied in cases where there is a definite presence of symmetry in the object and the estimated pose is already notably precise. Otherwise, using $e_{\text{ADD-S}}$ becomes irrelevant since the estimation is advantaged.

5.4 Quantitative evaluation

¹In this context, the vector x^* represents a vector that has been extended by appending a 1, specifically for the purpose of matrix multiplication.

6 Ways of improvements

6.1 Specialized spacecraft training set

6.2 Improved object detection algorithms

Rely more on the 3D model (for now only the size) and the segmented images, would optimize for symmetric and irregular shaped spacecrafts

6.3 Robustness to occlusion

7 Conclusion

Limitations Acknowledgments My personal contribution
